#### THIS PAPER

--represents an effort by the Society to deliver technical data direct from the author to the reader with the greatest possible speed. To this end, it has had none of the usual editing required in more formal publication procedures.

Readers are invited to submit discussion applying to current papers. For this paper the final date on which a discussion should reach the Manager of Technical Publications appears on the front cover.

Those who are planning papers or discussions for "Proceedings" will expedite Division and Committee action measurably by first studying "Publication Procedure for Technical Papers" (Proceedings — Separate No. 290). For free copies of this Separate—describing style, content, and format—address the Manager, Technical Publications, ASCE.

Reprints from this publication may be made on condition that the full title of paper, name of author, page reference (or paper number), and date of publication by the Society are given.

The Society is not responsible for any statement made or opinion expressed in its publications.

This paper was published at 1745 S. State Street, Ann Arbor, Mich., by the American Society of Civil Engineers. Editorial and General Offices are at 33 West Thirty-ninth Street, New York 18, N. Y.

#### ANALYSIS OF THE VIERENDEEL GIRDER BY BALANCING THE PANEL MOMENTS

A. T. Diwan, A.M. ASCE1

#### SYNOPSIS

A special type of panel displacement which produces moments in the chords of the distorted panel only and no else where in the Vierendeel is developed. This enables the analysis to be done by successive operations of joint rotations and special panel displacements, by which the moments in the joints and in the panels are successively balanced.

#### INTRODUCTION

The Vierendeel girder is usually regarded as one of the highly redundant constructions, for which the analysis by the classical methods necessitates the solution of 3n equations of continuity where n is the number of panels in the girder. This in fact limits the practical possibility of using the classical methods successfully for the analysis of the Vierendeel girder, and the designer readily welcomes any other method of analysis in which these simultaneous equations can be avoided. In a previous work the author developed an exact solution for the Vierendeel and other similar systems, of successive panels, using a new concept of "Equivalent Elastic Panels." In that method the Vierendeel is reduced to an equivalent system of "Virtual" panels and the analysis is directly made without the use of simultaneous equations.

In this paper, a relaxation method for the analysis of the Vierendeel girder

using a special type of panel displacement is presented.

The difficulty in using the moment distribution method originally developed by Prof. H. Cross for the analysis of the Vierendeel has so far been in the fact the joints of the girder undergo certain displacements as well as rota-

tions before the final loaded position is taken.

To allow for the joint translations in the case of a Vierendeel with parallel chords is in fact quite simple, since any relative vertical translation may be imposed on the vertical sides of any panel without producing moments except in the chords of that panel. In the general case of the Vierendeel with nonparallel chords such a relative upward or downward translation in the vertical side of any panel is accompanied by a horizontal displacement in the top joints which sets up heavy moments in the vertical members. If, however, this translation is associated with some joint rotations, a special type of panel displacement is obtained which leaves all panels to each side of the displaced

<sup>2. &</sup>quot;Mathematical Analysis of Continuous Arches and Frames Using the Principles of Un-loaded Elastic Models" by A. F. Diwan. Thesis presented for the degree of Ph.D. at the University of London 1948.

panel free from bending moments. This enables us to produce the required displacement in any panel without affecting the stresses or the equilibrium of other panels.

By successive operations of joint rotations and special panel displacements, all initial fixations on the Vierendeel are gradually relaxed to any required degree of accuracy, as will be fully explained hereafter. The application of the method to the following cases is illustrated;

- 1. B.M.D for any case of loading.
- 2. Direct evaluation of influence lines by the Muler Breslau's principle.
- 3. Effect of variable temperature changes, in the Vierendeel.

The method may be applied to other types of structures and to Vierendeel girders with variable cross sections.

#### Part 1. THEORY

#### 1. The Special Panel Displacement:

Fig. (1-a) shows the dimensions and relative stiffness of members for panel ABCD in a Vierendeel girder.

Let joint D be displaced vertically upwards to D without allowing rotation in any joint of the panel. If the axial deformation of the members is disregarded; C will move to  $C_1$ , fig (1. b), such that:

$$DD_1 = CC' = a.s; C'C_1 = a.b - fig (1.e)$$

"a" is any arbitrary constant.

The moments produced in the panel will be as shown in fig. (1.b).

If on the other hand, joints C and D are rotated through an angle  $\emptyset$  = ab; with no joint translation, the bending moment produced in the panel will be as shown in figure (1.c).

When the joint translation in fig. (1.b) is associated with the joint rotation in fig. (1.c) a type of displacement will result in panel ABCD, as shown in figure (1.d), in which bending moments will be set up in the chords AC and BD only while the verticals CD and AD remain free from bending moments. In fact, the final displacement of the vertical side CD may be regarded as a vertical upward translation  $\delta$  = a.s, plus a rotation of the whole member through an angle  $\emptyset$  =  $\frac{ab}{h_1}$  about the new position D<sub>1</sub> to which joint D has moved. Such

a displacement would produce no moments in CD which remains un-distorted. All other panels to the right of CD will also remain unstressed. They are simply pushed as a rigid body upwards through a distance  $\delta$  = a.s; then rotat-

ed about joint  $D_1$  through an angle  $\emptyset = \frac{ab}{h_1}$ . This is shown in figure. (2.a).

Referring to figure (1.d), the bending moments produced in chords AB and BD by the special displacement imposed on panel ABCD are:

$$M^{ac} = M_1 = 2k_1 a \left(3 + \frac{4b}{h_1}\right)$$

$$M^{ca} = M_2 = 2k_1 a \left(3 + \frac{2b}{h_1}\right)$$

$$M^{bd} = M_3 = 2k_2 a \left(3 + \frac{b}{h_1}\right)$$

$$M^{db} = M_4 = 2k_2 a \left(3 + \frac{2b}{h_1}\right)$$
(1)

Eqns (1) may be written in the form:

$$\begin{array}{c} M_1 = a_1k_1 \ (2h_1 + h_2) \\ M_2 = a_1k_1 \ (h_1 + 2h_2) \\ M_3 = a_1k_2 \ (2h_1 + h_2) \\ M_4 = a_1k_2 \ (h_1 + 2h_2) \end{array}$$
 (2) In which  $a_1 = \frac{2a}{h_1}$ 

From Equations. (2) it follows that:

$$M_1: M_2 = M_3: M_4 = (2h_1 + h_2): (h_1 + 2h_2)$$

This means that;

 Points G<sub>1</sub> and G<sub>2</sub>, where the bending moment is zero in chords AC and BD, will lie on a vertical line G<sub>1</sub>G<sub>2</sub>.

Line G1G2 will pass through the centre of the plane area ABCD.
 This easily fixes the ratio of the moments M1: M2 or M3: M4.

3. The moments in the top and bottom chords along any vertical section are directly proportional to the stiffness  $k_1$  and  $k_2$  of the chords. This again fixes the ratio  $M_1:M_3$  or  $M_2:M_4$ .

Since no bending moments are produced in the vertical members of the Vierendeel truss due to the displacement imposed on panel ABCD, no horizontal forces are set up in chords AC and BD. The external action on the panel necessary to produce this displacement will consist of the four moments  $M_1$ ,  $M_2$ ,  $M_3$  and  $M_4$  plus two vertical shearing forces  $V = -\sum M + S$  as shown in figure (2.b.).

#### 2. Condition for the Static Equilibrium in the Panel.

Consider figure (3-a) which shows an intermediate panel in a Vierendeel truss under any case of loading. Only the chords AC and BD of panel ABCD are shown, the rest of the Vierendeel including the vertical sides AB and CD being removed and substituted by its action on the chords at A,B,C and D. The moments and forces in figure (3) represent the action of the joints on the chords.

Taking moments at B say, we get for the equilibrium of the panel:

$$\Sigma M_c + Q^d \times s + P.a - H.b = 0$$
or
$$\Sigma M_c + Q'.s - H.b = 0$$
in which:
(3)

 $\Sigma M_{\rm C} = M_1 + M_2 + M_3 + M_4$ 

- = sum of the moments applied by the joints on the chords. Clockwise moments are positive.
- Q' = modified shearing force in panel ABCD, obtained on the assumption that the intermediate loads in the panel, if any, are substituted by their simple action at the ends of the chord BD. This will not change the end reactions in the Vierendeel. Q' will then be equal to the sum of all forces to either side of any intermediate section in the panel, and will be constant throughout the panel. Q' is positive when it produces clockwise rotation.
- H = horizontal force acting on the top joint of the shorter side of the panel. It is positive when it acts from left to right.

  H equals the sum of the shearing forces in the vertical members to the right of CD in figure (3.a), or to the left of CD in figure 3.b, including CD itself. The shearing force in any vertical member equals  $\frac{\sum M_{V}}{h}$  where:
- $\Sigma M_v$  = sum of the two moments applied by the top and bottom joints on the vertical member.

h = length of the vertical member.

Equation (3) applies also to panel ABCD in figure (3.b). When no intermediate loads act between the panel points, equation (3) reduces to:

$$\sum M_c = Q.s - H.b = o (3-a)$$

## 3. Balancing Coefficients for the Moments in the Panel. (Fig. 2)

If the sum  $\Sigma Mc$  of the moments in the chords of the panel does not satisfy eqns. (3) or (3.a), the panel is said to be unbalanced. The unbalanced moment in the panel will equal to  $M^*$  where.

$$M^* = (\Sigma M + Q.s - H.b.)$$
 (4)

To satisfy the panel equilibrium it becomes necessary to reduce the chord moments  $\Sigma M_c$  by an amount equal to  $M^*$ . This is done by imposing a displacement similar to that in figure (2) on the panel. The magitude and direction of the displacement will depend on the value and sign of the unbalanced moment  $M^*$ . If cs = distance of line  $G_1G_2$  passing through the centre of the panel surface from the longer side AB, where s = length BD.

$$\therefore C = \frac{2h_1 + h_2}{3(h_1 + h_2)}$$
 (5)

and  $(1-c)s = distance of G_1G_2$  from the shorter side CD. n = some arbitrary constant.

then:

or

$$M_{1} = nck_{1}$$

$$M_{2} = n(1-c)k_{1}$$

$$M_{3} = nck_{2}$$

$$M_{4} = n(1-c)k_{2}$$

$$\sum M = n(k_{1} + k_{2})$$

$$n = \frac{\sum M}{k_{1} + k_{2}}$$

For the displacement necessary to balance the panel;  $\Sigma M = -M^*$ 

Therefore:

$$M_{1} = -M^{*} \cdot \frac{ck_{1}}{k_{1} + k_{2}} = -\epsilon_{1} M^{*}$$

$$M_{2} = -M^{*} \cdot \frac{(1-c)k_{1}}{k_{1} + k_{2}} = -\epsilon_{2} M^{*}$$

$$M_{3} = -M^{*} \cdot \frac{ck_{2}}{k_{1} + k_{2}} = -\epsilon_{3} M^{*}$$

$$M_{4} = -M^{*} \cdot \frac{(1-c)k_{1}}{(k_{1} + k_{2})} = -\epsilon_{4} M^{*}$$
where:
$$\epsilon_{1} = \frac{ck_{1}}{k_{1} + k_{2}}$$

$$\epsilon_{2} = \frac{(1-c)k_{1}}{k_{1} + k_{2}}$$

$$\epsilon_{3} = \frac{ck_{2}}{k_{1} + k_{2}}$$

$$(1-c)k_{3}$$

$$(7)$$

The terms  $\epsilon_1$ ,  $\epsilon_2$ ,  $\epsilon_3$  and  $\epsilon_4$  are called the balancing coefficients for the panel. To balance the panel, the moment - M\* is simply distributed on the chords according to these coefficients.

#### 4. Proposed Method of Analysis:

In the final displaced position of the Vierendeel truss under any case of loading, the moments produced in the members must satisfy the equilibrium condition for all panels and joints.

For each panel: 
$$\sum M_c + Q.s - H.b = 0$$
 (a)  
For each joint:  $\sum M$  = 0 (b)

Starting with condition (a), it is seen that the modified shear value  $Q^l$  due to any particular case of loading, is known for all panels, since the Vierendeel is externally statically determinate. In the initial unloaded position of the Vierendeel, with no moments yet produced,  $\Sigma M_C = H = zero$  for all panels. The unbalanced moment in each panel is therefor equal to  $Q^l$ .s. This moment is distributed according to the balancing coefficients  $\epsilon_1$  to  $\epsilon_4$  between the chords of the panel. We notice that such balancing of any panel will not affect other panels in the Vierendeel, so that we can balance all the panels by balancing each individual panel separately. In doing so we have in fact imposed on each panel a special displacement of the type proposed in figures (i-d), or (2-a).

In the case when an influence line is to be drawn, or when some temperature

effects are to be studied or so, no reactions are set up at the supports, yet special moments must be applied in some manner as will be seen later. In such cases Q' = 0 in all panels; and the unbalanced moment to start with in any panel equals the sum of the moments initially imposed in the chords of the panel, if any.

Now that condition (a) is satisfied for all panels, we proceed to condition (b) for the joints. Each joint is allowed to rotate while all other joints are kept fixed until the unbalanced joint moment is distributed among the near ends of the two chords and vertical framing into the joint according to their stiffness values k. Moments equal to half the distributed moments are carried over to the far ends of the members.

As a result of these joint rotations, moments are produced in the verticals, and this in turn gives rise to horizontal forces H in the panels originally taken equal to zero. In addition to this, the chord moments are changed by the distributed and carry-over moments developed by the joint rotations. The result in that condition (a) for the panel equilibrium is no longer maintained, and it needs readjustment. The new unbalanced moment in each panel will be.

$$\mathbf{M}^* = \sum \mathbf{M}_{\mathbf{C}}^{\mathbf{i}} - \mathbf{H}_{\mathbf{D}}^{\mathbf{i}}$$

Where  $M_c^{\prime}$  and  $H^{\prime}$  are chord moments and the horizontal force produced by the previous step of joint rotations. This moment is distributed among the chords according to the chord balancing coefficients  $\epsilon$ . This is followed by distributing the unbalanced moments at the joints. The process continues to the required degree of accuracy. It will be seen from the examples shown hereafter that the convergence of the method is remarkable.

#### Part II. APPLICATIONS

The method is now to be applied for the analysis of the Vierendeel truss shown in figure (4.a). The same truss was dealt with before by the author using the method of "Equivalent Elastic Panels." It is interesting to compare both results and see the remarkable agreement.

The dimensions and relative stiffness values  $k = \frac{EI}{L.EI_0}$  for all Vierendeel members are given in the figure. EI for the top chord members equals 3EI for the bottom chord and vertical members. EI $_0$  is any arbitrary value taken equal to  $\frac{1}{3}$  EI of the bottom chord or  $\frac{1}{9}$  EI of the top chord. In fig. (4.b), half the values of the distribution factors due to joint rotations are shown. These in fact are the carry over factors for the moments developed at the far ends of the members. To save time and space the distributed moments at the joints produced by the joint rotations are not computed. Only the carry over moments are entered in the tabulated solutions given hereafter. In the final step however, the total unbalanced moment at each joint is distributed among the members framing into the joint.

The balancing coefficients for the panels are also shown in figure (4.c). The value c giving the position of the centre of area for each panel is first

 <sup>&</sup>quot;Mathematical Analysis of Continuous Arches and Frames Using the Principles of Un-loaded Elastic Models" by A. F. Diwan. Thesis presented for the degree of Ph.d. at the University of London. 1948.

determined from equation (5); then coefficients  $\epsilon$  are computed from eqns. (7).

$$c = \frac{2h_1 + h_2}{3(h_1 + h_2)}$$

For the first panel;

$$h_1 = 1.2$$
;  $h_2 = 2.28$ ,  $k_1 = 2.82$ ,  $k_2 = 1.0$   
 $\therefore c = \frac{2(1.2) + 2.28}{3(1.2 + 2.28)} = 0.448$ .

From eqns. 7;

$$\epsilon_1 = 0.448 \ (\frac{2.82}{1 + 2.82}) = 0.330$$
 $\epsilon_2 = 0.552 \ (\frac{2.28}{1 + 2.28}) = 0.408$ 
 $\epsilon_3 = 0.448 \ (\frac{1}{1 + 2.28}) = 0.117$ 
 $\epsilon_4 = 0.552 \ (\frac{1}{1 + 2.28}) = 0.145$ 

#### 5. B.M.D. due to a load P = 7000 lb at L.

Table (1) shows the necessary computations for the analysis of the Vierendeel under a load P = 7000 lb. at joint L. In the initial position, with no moments yet produced, the unbalanced moment in each panel equals Q.S.

This equals - 2000 x 3 = -6000 lb. ft in the five panels to the right and  $5000 \times 3 = 15000$  lb. ft in the two panels to the left. The unbalanced moments are distributed and entered in line (1) in the table. Next the joints are balanced, and the carry over moments are entered in line (2). For joint B for example; the unbalanced moment is - (4950 + 5850) = -10800 lb. ft. The carry over moment produced at end  $\epsilon$  of chord BC will be equal to 0.206 (10800) = 2225 lb. ft. Needless to say that the distributed moment produced in end B of BC attached to joint B is twice the carry over moment; i.e. 4450 lb. ft.

In step (3) the panels are balanced again. Consider the first panel ABJK. The unbalanced moment due to the carry over moments only in step (2) will be:

$$H^{'} = (780 + 1440) \div 1.2 = 1850 \text{ lb.}$$
  
 $\Sigma M'_{C} = (2160 + 1625 + 570 + 310) = 4665 \text{ lb. ft.}$   
 $A^{*} \cdot M^{*} = 4665 - 1850 (1.08) = 2668 \text{ lb. ft.}$ 

The total unbalanced moment in the panel is actually three times this moment, since the distributed moments not tabulated in step (2) are double the shown carry over moments. Therefore; the total unbalanced moment in the first panel will be:

$$M* = 3 \times 2668 = 8004 \text{ lb. ft.}$$

For the second panel BCKL; the carry over moments give:

$$H' = 1850 + (745 + 1020) \div 2.28 = 2630 \text{ lb.}$$
  
 $\Sigma M_C = (600 + 2225 + 177 + 570) = 3572 \text{ lb. ft.}$ 

The unbalanced moment will be:

$$M^* = 3 [3572 - 0.72 (2630)] = 5000 lb. ft.$$

Table (1). Moment Computations For a Single Load P = 7000 lbs. at L .

This is distributed between the chords according to the balancing coefficients; for example;

$$M^{bc}$$
 = -0.39 (5000) = -1950 lb. ft.  
 $M^{cb}$  = -0.354 (5000) = -1770 lb. ft.

These moments are entered in line 3.

As we proceed towards the centre panel, "b" decreases and the term (b.H) diminishes. For the central panel DEMN the unbalanced moment equals three times the sum of the carry over moments. $^4$ 

4. Notice that the sum of the shears in all verticals at this stage will not be zero. Some sort of support capable of giving a horizontal reaction only may

Next the unbalanced moments at the joints are distributed and the carry over moments entered in line 4, followed in line 5 by the moments necessary to re-establish the panel equilibrium.

Finally in line 18, we enter the total distributed moments at the joints. For joint B say, the sum of the moments in lines 1 to 17 is 12820 lb. ft., to be distributed to BA, BC and BK in the ratios - .40, - 0.412 and - .188 respectively.

be assumed to exist at joint D to maintain the equilibrium of the top chord against the unbalanced horizontal force H. In any panel, H by definition is the horizontal force acting at the top joint of the shorter side. This will not be affected by the reaction of this support. As we proceed with the relaxation process, the reaction set up by the artificial support will gradually diminish, and should finally disappear at last.

The final moments are obtained by summation, and are given in table 2 for comparison with those previously obtained by the method of "Equivalent Elastic," which is referred to in the table by the exact method. The agreement of both results is indeed remarkable. The final B.M.D. is also shown in figure. (5).

#### 6. Direct Evaluation of Influence Lines.

According to the Muler Bruslau's principle, the influence line for moment, thrust or shear at any section is the deflection line of the loaded chord produced by a unit relative rotation, axial translation or unit relative translation normal to the axis, imposed at that section. To impose such a relative displacement the Vierendeel is cut at that section until the required displacement is produced, after which full continuity is re-established at the section.

Since the Vierendeel is externally statically determinate, no reactions are produced at the supports due to the imposed relative displacement. All joints of the Vierendeel are initially kept fixed against rotation (and if possible against translation also) when the relative displacement is being imposed. The following two examples will illustrate the application of the method.

### 6-A. Influence line for the moment Mcd.

While all joints are kept fixed, a unit rotation is produced in end C of the chord CD. Figure (6) shows the Vierendeel with the deflected member CD only and the resulting bending moment diagram.

$$\mathbf{M}^{cd} = 4\mathbf{k}$$
,  $\emptyset = 4\mathbf{k} = 4$  (2.98) = 11.92 " $\emptyset = \text{unity}$ "  
 $\mathbf{M}^{dc} = 2\mathbf{k}\emptyset = 2\mathbf{k} = 2$  (2.98) = 5.96

These moments are entered in table (3); line (1). No moments are yet produced any where in the Vierendeel since no reactions are set up at the end supports. Only panel CDLM is now unbalanced; and the unbalanced moment is:

$$M* = 11.92 + 5.96 = 17.88$$

This moment is distributed according to the coefficients  $\epsilon$  and the balancing moments are entered in line 2. In line 3 are the carry over moments and in line 4 the new balancing moments in the panels. Finally in line 15 we have the total distributed moment at each joint.

<sup>5.</sup> Thesis for Ph.D. London University. A. Diwan. 1948.

For convenience, all moments in table (3) are multiplied by 1000. The final moments are given in table (4) and may be compared with these obtained by the method of "Equivalent Elastic Panels". The influence line is shown in figure (7).

#### 6-B. Influence Line for the Thrust in Chord LM.

We need to produce a unit relative axial translation in chord LM. Two possible ways for producing this displacement are shown in figure (8). In case (a) joints J, K and L are all translated to the left through the same distance without rotation.

In case (b), the 4 panels to the right are rotated as a rigid body through an angle =  $-\emptyset$  about joint D and the two panels to the left are rotated through an angle  $-\emptyset$  about joint C.

$$\emptyset = \frac{1}{(h_1 + h_2)} = 1 \div 6.36 = 0.157.$$

The same rotations  $\emptyset$  and -  $\emptyset$  are also imposed on the ends L and M respectively of chord LM which is supposed to be detached from the Vierendeel during the panel rotations about C and D. Of course it is supposed that after the relative translation is imposed, chord LM is reconnected rigidly to the Vierendeel. (by some rigid arms.) The bending moments produced in the chords CD and LM due to the translation in case (b) are as shown in the figure, in which;

$$M^{cd} = -M^{dc} = 2k_1 \emptyset = 2(2.98) (0.157) = 0.940$$
  
 $M^{lm} = -M^{ml} = 2k_2 \emptyset = 2(0.157) = 0.314$ 

No moments are produced anywhere else in the Vierendeel.

It is not necessary that the imposed rotations at C and D should be equal and opposite, yet it is more convenient to do so since this would make panel CDLM balanced under the initial set of moments.

Type (b) for the imposed displacement is more favourable than type (a) and is used in the tabulated computations given hereafter (table 5).

The initial moments are entered in line 1. All panels, including CDLM, are balanced. So we proceed to evaluate the carry over moments in line 2, then the balancing moments in line 3, and finally the total distributed moments in line 20.

Table (6) shows the final moments, obtained by both relaxation and exact method of "Equivalent Elastic Panels." The influence line is shown in figure (9).

#### 7. Rise of Temperature in Bottom Chord.

This is equivalent to a relative axial translation  $\delta$  similar to that in figure (8) in the bottom chords of all the panels in the Vierendeel; such that  $\delta = \alpha t s$ .

The computations shown in table 7 corresponding to these imposed translations are similar to those in the previous problem, table 5.

The Vierendeel is symmetrical, and the computations correspond to the

All moments are multiplied by 1000/El

left half of the Vierendeel only. The displacement  $\alpha$  is taken in the computations equals  $\frac{(10)^4}{EIO}$ .

The final moments are given in table (8), and are shown in fig (10).

#### CONCLUSION

The method just outlined is applicable to the case when the cross section of the members vary between the joints. The same type of special panel displacement is adopted, but both carry-over factors and balancing coefficients for the panel moments will be different, yet, they can be easily evaluated.

The rest of the computations will be unchanged.

#### PROCEEDINGS-SEPARATES

The technical papers published in the past year are presented below. Technical-division sponsorship is indicated by an abreviation at the end of each Separate Number, the symbols referring to: Air Transport (AT), City Planning (CP), Construction (CO), Engineering Mechanics (EM), Highway (HW), Hydraulics (HY), Irgation and Drainage (RI), Power (PO), Sanitary Engineering (SA), Soil Mechanics and Foundations (SM), Structural (ST), Surveying and Mapping (SU), and Waterways (WW) divisions. For titles and order coupone, refer to the appropriate issue of "Civil Engineering" or write for a cumulative price list.
